ABSTRACTS FOR  
SELECTED PAPERS**“Rural householdsâ participation in charcoal production in Zambia: Does agricultural productivity play a role?”**

The study uses a nationally representative dataset of smallholder farmers in Zambia to determine the effect of agricultural productivity on householdsâ participation in charcoal production. An instrumental variable probit approach is applied to account for the endogeneity of agricultural productivity in household's charcoal participation decision. We find a negative and significant effect of agricultural productivity on household's likelihood of participation in charcoal production. Results also show that higher education, income, asset value, and participation in off-farm employment opportunities reduce the likelihood of participation in charcoal production. Therefore, interventions seeking to reduce charcoal production in rural Zambia could benefit from improving smallholder agricultural productivity, incomes, asset base, and off-farm employment creation. However, interventions need not lose sight of other important macro-level factors.

**“Staple crop pest damage and natural resources exploitation: fall army worm infestation and charcoal production in Zambia”.**

Sub-Saharan Africa (SSA) is home to the highest rates of deforestation in the world, pushing the research community to understand its drivers. One driver may be negative agricultural shocks that drive households to consume natural resources as a coping mechanism. This paper uses primary household panel data from Zambia to estimate the effect of the introduction of an agricultural pest, fall armyworm (FAW) on charcoal production. We exploit exogenous variation in the intensity of exposure to FAW across households and years to identify their effect and find a positive and significant effect of FAW on charcoal production and deforestation. We find that FAW in the village increases the probability of producing charcoal by 3.48 percentage points, from 22 percent to 25 percent. The results also indicate that when methods to mitigate FAW damage such as reducing the share of maize, migration for off-farm employment opportunities and chemical spraying are available, farmers are less likely resort to charcoal production as a coping strategy. Effects are robust to linear including region-specific time trends and instrumental variables for FAW presence. The results suggest that policy interventions to mitigate agricultural production shocks could also have the benefit of reducing charcoal production and deforestation.

**“The effect of invasive pests on food security: An understudied effect of climate change”.**

Global agricultural production and food security are threatened by insect pests. Pest invasions have been exacerbated by climate change, as temperatures increase both the range and the appetite of the insects. While the direct effect of climate change on agricultural production has received a lot of attention in the literature, less work estimates the indirect effect of climate change on agricultural production and food security through the insect pests which are exacerbated by climate change. In this paper, we use the example of the introduction of Fall armyworms (FAW) to Africa to study the effect of insect pests on agricultural production and food security in the face of climate change. We use a panel of primary farmer data to evaluate the effect of this pest and analyze which characteristics make farmers more vulnerable to food insecurity in the face of a FAW invasion. We find that FAW decreases maize yield by 39.8 percent and can increase food insecurity by up to 10 percent. Further, we find that increased temperatures are related to higher FAW incidence. On the other hand, we find that farmers can mitigate the effect of fall armyworms through planting early and planting drought-tolerant hybrids. The effects are robust to time-invariant household unobservable characteristics. Specifically, we find that forecasts of increased temperatures on maize yield underestimate the potential effect of climate change by about 0.8 percent if they do not include the loss in yield from increased pest pressure. This paper demonstrates the understudied threat of climate change through insect pests on food production and food security, suggesting that climate change poses greater threats to future food security than previously measured.
